<b>(54) Title: ANTI-CROSS CONTAMINATION VALVE AND FLUID DELIVERY SYSTEMS USING SAME</b>			
<b>(57) Abstract</b>			
<p>An anti-cross contamination valve (30) for use in medical fluid delivery systems comprises a valve housing (42) having a first port (34), a second port (35), and a third port (36) that open into a hollow interior (41). A valve body (31) is rotatably mounted within the hollow interior (41) and has at least one fluid passageway therethrough. A knob (32) is attached to the valve body (31) and extends outside of the valve housing (42). At least one fluid passageway opens the first port (34) to the third port (36) when the valve body (31) is rotated to a first position, and the second port (35) opens to the third port (36) when the valve body (31) is rotated to a second position. In order to prevent the possibility of cross contamination, the valve includes stop barriers (38) and/or a special passageway/port geometry that prevents the possibility of the first port (34) coming into fluid communication with the second port (35), or vice versa.</p>

ANTI-CROSS CONTAMINATION VALVE AND FLUID DELIVERY  
SYSTEMS USING SAME

5

TECHNICAL FIELD

The present invention relates generally to medical fluid delivery systems, and more particularly to medical fluid delivery systems utilizing a valve that prevents cross contamination between fluid sources connected to the valve.

10

BACKGROUND OF THE INVENTION

Multi-port fluid transfer valves have long been known in the art. These valves typically have three or more ports and the ability to selectively open the various ports to one another in different combinations depending on the number of ports. For example, U.S. Patent No. 3,048,192 to Murphy, Jr. shows a surgical valve with three or four ports and the ability to open any pair of ports to one another. Likewise, U.S. Patent No. 4,900,322 to Adams shows a valve with four ports and the ability to selectively connect different pairs of the ports. While there are numerous medically related procedures in which it is desirable to cross connect various ports of a valve, there are some situations in which cross connection between certain ports creates the potential for undesirable cross contamination, undermining a particular medical procedure and/or preventing or delaying a patient from receiving a desired treatment.

Fig. 2 shows a prior art Y-type blood/solution set 10' utilized in a variety of circumstances to transfuse fluids to a patient. While these blood/solution sets work satisfactorily in many situations, physicians often encounter cross contamination problems when a solution bag connected to bag connector 16a is allowed to flow into the fluid container attached to connector 16b, or vice versa.

One example situation might be when blood/solution set 10' is being utilized to deliver a medicated saline solution from a first bag connected to connector 16a, and a sudden emergency requires the quick delivery of blood or blood

product from a bag attached to connector 16b. In order to hasten the delivery of the blood to the patient, the physician may squeeze or mechanically compress the bag attached to connector 16b in order to increase the flow rate 5 of fluid through the filter and other components downstream from the bag. Unfortunately, in many such emergency situations, both clamps 18a and 18b are accidentally left open and the blood flowing through connector 16b is permitted to flow down through Y-connector 20 and back up 10 into the medicated saline solution bag attached to connector 16a, contaminating the medicated saline solution with whole blood or blood product. In this situation, the contaminated saline solution must be discarded, and the physician is left with guessing how much of the blood unit was lost to cross 15 contamination. At the same time, the transfusion of emergency blood to the patient has been delayed because of the blood flowing across to the saline bag rather than down through the filter and other components to the patient. Further precious time will likely be wasted in the time it 20 takes to close clamp 18a, remove the contaminated saline bag and attach a new medicated saline solution bag to connector 16a, which normally must be resumed after the blood unit has been delivered to the patient. While the prior art Y-type 25 blood/solution set 10' and the valves discussed above have the ability to avoid cross contamination, they include no fail-safe means for preventing cross contamination.

The present invention is intended to overcome the potential cross contamination problems associated with the prior art fluid transfer medical devices.

30

#### **SUMMARY OF THE INVENTION**

In one embodiment, the present invention comprises an anti-cross contamination valve having a valve housing with a plurality of first ports, and a third port that all open 35 into a hollow interior. A valve body is rotatably mounted within the hollow interior and has at least one fluid passageway therethrough. A knob is attached to the valve body and extends outside of the valve housing. The at least

one passageway includes a first fluid passageway that opens a first port to the third port when the valve body is rotated to a first position with respect to the valve housing, and closes a second port when the valve body is in its first position. Also, the at least one passageway includes a second fluid passageway that opens the second port to the third port when the valve body is rotated to a second position with respect to the valve housing, and the first port is closed when the valve body is in its second position. Finally, the valve includes some means for preventing the at least one fluid passageway from opening the first port to the second port.

#### BRIEF DESCRIPTION OF THE DRAWINGS

15 Fig. 1 is a schematic illustration of an anti-cross contamination Y-type blood/solution set according to one embodiment of the present invention.

Fig. 2 is a schematic view of a Y-type blood/solution set according to the prior art.

20 Fig. 3 is an isometric view of an anti-cross contamination valve according to the present invention.

Fig. 4a is a sectioned top view of the anti-cross contamination valve of Fig. 3 view along section line 4a-4a.

Fig. 7 is a sectioned top view of an anti-cross contamination valve according to still another embodiment 35 the present invention.

Fig. 8 is a sectioned top view of an anti-cross contamination valve according to another embodiment of the present invention.

Fig. 9 is a schematic illustration of an anti-cross contamination Y-type blood/solution set according to another embodiment of the present invention.

**DETAILED DESCRIPTION OF THE  
PREFERRED EMBODIMENTS**

Referring again to Fig. 2, a prior art Y-type blood/solution set 10' includes two lengths of IV tubing 11 and 12, each with a clamp 18 mounted thereon and having a bag connector 16 with a protective cap 17 attached to one of its ends. The other ends of tubing 11 and 12 merge into a Y-connector 20 that opens into a filter 19. A drop former 21 and drip chamber 22 are attached to the outlet end of the filter. A third length of IV tubing 13 extends from the bottom of drip chamber 22 to injection port 27. A slide clamp 24 and regulating or roll-type clamp 25 are mounted on IV tubing 13. Finally, a fourth length of IV tubing 14 is connected at one end to injection port 27 and at its other end to a connector 28, such as a Luer connector, that includes a protective cap 29, which is removed prior to use. In some Y-type blood/solution sets, the filter is omitted from the set. In such cases, an auxiliary filter can be attached intermediate the bag and bag connector 16 if needed.

Referring now to Fig. 1, an anti-cross contamination Y-type blood/solution set 10 according to the present invention is shown directly adjacent a prior art set 10'. Anti-cross contamination set 10 includes many of the same features, which are identically numbered, as its counterpart prior art set 10'. In particular, set 10 includes a first length of IV tubing 11 with a bag connector 16b attached to one end and connected to a first port of an anti-cross contamination valve 30 at its other end. Bag connector 16b can be any type of connector which facilitates connection of tubing 11 to a fluid container. For instance, connectors 16b might be an ordinary bag spike that includes a fluid

tight protective cap 17, which is removed and discarded when bag connector 16b is actually attached to a fluid container, such as a blood or solution bag. A second length of tubing 12 likewise includes a bag connector 16a at one end and is attached to a second port of anti-cross contamination valve 30 at its other end. The outlet port of valve 30 is attached to a filter 19, which in turn is attached to a drop former 21 and a drip chamber 22. A third length of IV tubing 13 extends from the bottom of drip chamber 22 to an injection port 27. A typical slide clamp 24 and regulating clamp 25 are mounted on the third length of tubing 13. Regulating clamp 25 has the ability to control the flow rate of fluid through the device to the patient, while slide clamp 24 gives the ability to quickly pinch off tubing 13 in order to shut off flow completely. Injection port 27 can be any type known that permits the injection of fluid or intravenous medication into the fluid flow through the set to the patient. A fourth length of IV tubing 14 is attached at one end to injection port 27 and to a connector 28, such as a Luer connector, at its other end. Until use, connector 28 preferably includes a protective end cap 29. As can be seen, anti-cross contamination set 10 is substantially identical to the prior art set 10' except that clamps 18a and 18b of the prior art set have been eliminated and the Y-connector 20 of the prior art has been replaced by an anti-cross contamination valve 30 according to the present invention.

Cross contamination between the respective fluid containers attached to connectors 16a and 16b is permitted in prior art sets 10' whenever both clamps 18a and 18b are left open, because Y-connector 20 is simply a three-way intersecting passageway. Anti-cross contamination set 10, on the other hand, includes a valve 30 which cannot permit fluid flow between the respective fluid containers attached to bag connectors 16a and 16b. Valve 30 is shown in its second position in which knob 32 and arrowhead 33 point in the direction of IV tubing 12. This indicates to the user that only the fluid container attached to bag connector 16a

is in fluid communication with the filter 19 and other downstream components of the set. By rotating knob 32 to the right to its first position (shown in shadow) in which arrowhead 33 points in the direction of tubing 11, the user 5 knows that only tubing 11 is then open to flow through the valve. Also shown in shadow in Fig. 1 is knob 32 of valve 30 in its middle or third position in which both the inlet port connected to tubing 12 and the inlet port connected to tubing 11 are closed to filter 19 and the other lower 10 components of the set. Thus the user of anti-cross contamination Y-type set 10 can quickly tell which, if any, of the fluid containers attached to bag connector 16a and 16b are open to flow, by merely glancing at the position of arrowhead 33 on valve 30. This is not possible with the 15 prior art set 10' which left the user guessing which, if any, of the fluid containers are open to flow based upon a glance at the relative position of the rollers in clamps 18a and 18b.

Clamps 18a and 18b of the prior art permit one to 20 regulate the rate of flow to filter 19. Flow regulation in anti-cross contamination Y-type set 10 is accomplished simply by rotating knob 32 slightly toward the middle closed position so that the internal passage through valve 30 is only partially opened to the respective port. (See Fig. 4).

25 The various features and internal structure of anti-cross contamination valve 30 are illustrated in Figs. 3 and 4a. Valve 30 includes a cylindrically shaped valve housing 42 having a first inlet port 34, a second inlet port 35 and an outlet port 36 that all open into a hollow interior 41.

30 Each of the ports includes a connector 37, such as a Luer lock connector, which facilitate attachment of the various ports to a length of tubing. A cylindrically shaped valve body 31 is sized and positioned to substantially fill hollow interior 41. Valve body 31 includes a first passageway 43 35 and a second passageway 44 therethrough that are substantially parallel to one another. A knob 32 is attached to the upper side (not shown) of valve body 31, and facilitates rotation of the same within hollow interior 41.

The various components of valve 30 are preferably molded from a suitable plastic of a type known in the art.

Figs. 3, 4a and 4b show the valve in its closed position so that neither first inlet port 34 nor second 5 inlet port 35 are open to outlet port 36. Stop barriers 38 and 39 restrict the rotational movement of valve body 31 within valve housing 42. In particular, since knob 32 extends over the side of valve housing 42, counterclockwise rotation of valve body 31 is stopped when knob 32 encounters 10 left stop barrier 38, as shown in Fig. 1. When in this position, the passageway 43 permits fluid communication between first inlet port 34 and outlet port 36. Likewise, clockwise rotation of valve body 31 is stopped when knob 32 encounters right stop barrier 39. Valve 30 can be operated 15 with one hand by simply placing one finger on one of the stops 38 or 39 and another finger on the side of knob 32, and then simply pinching the fingers toward one another until knob 32 abuts one of the stops. Flow through valve 30 can be slowed or regulated by rotating knob 32 slightly away 20 from one of the respective stop barriers so that only part of the passageway 43 or 44 is in fluid communication with the respective inlet port. Thus, the valve of the present invention permits selective fluid connection through the 25 valve, regulation of that flow, and includes features that prevent the possibility of cross contamination between the inlet ports to the valve.

Fig. 4a shows a valve body 31 corresponding to the preferred embodiment of the anti-cross contamination valve of the present invention, and Fig. 4b shows an alternative 30 embodiment 30' having a single passageway therethrough. Valve 30' includes only a single passageway 40' instead of the parallel passages 43, 44 of the earlier embodiment. Valve 30' is similar in operation to the earlier embodiment in that one simply rotates valve body 31' via the attached 35 knob (see Fig. 3) in order to point upper portion 43' of passageway 40' toward one of the respective ports. Also like the earlier embodiment, side stops prevent valve body 31' from being positioned to permit cross contamination

between the inlet ports. Alternative valve anti-cross contamination valve 30' is less desirable than valve 30 of Figs. 3 and 4a because passageway 40' can in some cases allow the undesirable collection of fluid within the valve.

5 Referring now to Fig. 5, an anti-cross contamination extension tubing/valve assembly 50 according to the present invention is illustrated. Assembly 50 includes an anti-cross contamination valve 51 with a first port 53, a second port 54 and a third port 55 which is connected to a length 10 of IV tubing 58. If desirable, a connector 59, of a type known in the art, can be attached to the other end of IV tubing 58. Valve 51 is similar in function to the anti-cross contamination valve 30 discussed earlier except that it includes a single elbow passageway (not shown) which 15 aligns with indicia 57 on knob 56. Because first port 53 and second port 54 in valve body 52 are aligned, it is impossible for these two ports to be in fluid communication with one another through the elbow passageway. Thus, the fluid sources connected to first port 53 and second port 54 20 cannot cross contaminate one another since there is no way to open a fluid passageway between these respective ports regardless of the position of knob 56. Fig. 5 also shows knob 56 in shadow rotated clockwise 90° to the position in which first port 53 is opened to third port 55. Flow 25 regulation through valve 51 is accomplished by simply rotating knob 56 slightly off its fully opened position as shown so that only a portion of the passageway within valve body 52 is exposed to the respective ports. Unlike valves 30 and 30' discussed earlier, valve 51 includes no barriers 30 so that knob 56 can rotate 360°; however, the user can quickly note the position of the valve by observing the relative positioning of indicia 57 relative to the respective ports 53, 54 and 55.

35 Referring now to Fig. 6, an anti-cross contamination urological irrigation set 70 according to the present invention is shown. Urological set 70 is substantially similar to the anti-cross contamination Y-type blood/solution set 10 discussed earlier, except that it

preferably includes larger diameter irrigation tubing instead of the IV tubing of set 10, and also eliminates various components that are included in the blood/solution set 10 of the earlier embodiment. In particular, urological set 70 does not include a filter, drop former, injection port or drip chamber.

Urological set 70 includes a first length of irrigation tubing 71 having an appropriate connector 76 attached to one end and a port of anti-cross contamination valve 30 attached to its other end. Likewise, a second length of irrigation tubing 72 has an appropriate connector 76 attached to one end and another port of anti-cross contamination valve 30 attached to its other end. Preferably, both connectors include a protective fluid tight cap 77 that remains in place until use, at which time they are removed and discarded. A third length of irrigation tubing 73 has one end connected to outlet port 36 of valve 30 and its other end connected to a connector 79 of a type known in the art, such as a catheter adapter. A regulating clamp 75 is mounted on the third length of irrigation tubing 73 and acts as a secondary means of controlling the flow rate through the set.

Referring now to Fig. 7, a four-port version of an anti-cross contamination valve 80 according to the present invention is illustrated. Valve 80 includes a valve housing 81 having three first ports 82-84 and a fourth port 85, all of which open into the hollow interior of the valve housing. A cylindrically shaped valve body 86 is mounted within the hollow interior of valve housing 81 and includes three parallel passageways 87-89 therethrough. A knob (not shown) is attached to the valve body and extends outside of the valve housing so that valve body 86 can be rotated with respect to valve housing to selectively open the various ports. The size and geometrical distribution of first ports 82-84 along with the geometrical configuration of valve body 86 and its passageways 87-89 provide the means for preventing the passageways from opening any of the first ports to one another. In other words, there exists no

relative positioning of valve housing 81 with respect to valve body 86 in which any of the first ports 82-84 can be put in fluid communication with one another. The valve 80 is shown with first port 82 in fluid communication with 5 fourth port 85 via passageway 87. First ports 83 and 84 can be selectively opened to fourth port 85 by an appropriate rotation of valve body 86 to align passageways 88 and 89 with fourth port 85.

Referring now to Fig. 8, a five port version of an 10 anti-cross contamination valve 90 according to still another embodiment of the present invention is illustrated. Valve 90 includes a valve housing 91 having four first ports 92-95 and a fifth port 96 all of which open into a hollow interior 97. Valve body 98 is rotatably mounted within hollow 15 interior 97 and has four parallel passageways 99-102 therethrough. Valve 90 is shown with one of the first ports, namely port 94, in fluid communication with the fifth port 96 via passageway 101. Although any of the first ports 92-95 can be selectively opened to the fifth port 96, there 20 is no valve position which will allow any of the first ports 92-95 to communicate with one another. Thus, anti-cross contamination valve 90 includes fail-safe means for preventing any of the first ports 92-95 from opening to one another.

25 Referring now to Fig. 9, a Y-type blood/solution set 110 according to another embodiment of the present invention is illustrated. Set 110 is different from set 10 described earlier in that it includes an additional anti-cross contamination valve 30 and an additional filter. This 30 embodiment allows a healthcare provider to switch to a new filter without otherwise interrupting fluid flow to a patient. Most of the various components of blood/solution set 110 are identical and identically numbered to the components shown with respect to blood/solution set 10 described earlier. Like the previous embodiment, set 110 35 includes a first link of tubing 11 having a bag spike 16b attached to one end, and its other end attached to one of the first ports of an anti-cross contamination valve 30 of

the type shown and described in Figures 3 and 4. A second length of IV tubing 12 has a bag spike 16a attached to one end and its other end attached to one of the first ports of the anti-cross contamination valve 30. Both of the bag spikes include caps 17 that are removed when the set is actually put into use. The third ports 36 of the two anti-cross contamination valves 30 are connected to one another with a short segment of IV tubing 15. A pair of filters 19a and 19b are connected in parallel to the ports of the second 5 anti-cross contamination valve and merge back into a single IV tube downstream just before drop former 21 and drip chamber 22. A third length of IV tubing 13 extends from the bottom of drip chamber 22 to an injection port 27. A typical slide clamp 24 and regulating clamp 25 are mounted 10 on the third length of tubing 13. A fourth length of IV tubing 14 is attached at one end to injection port 27 into a Luer lock or other suitable connector 28 at its other end. 15 Until use, connector 28 preferably includes a protective end cap 29.

20 It is well known that over time a solution filter, such as solution filters 19a and 19b need to be replaced after a certain volume of fluid has passed therethrough. In the past, physicians and other healthcare providers necessarily had to stop the flow of fluid to a patient while the new 25 solution set having a new filter was connected to the patient. In the case of the present invention, the healthcare provider simply rotates the lower valve 30 to have the fluid pass through the other available filter 19b as shown. In some instances it might be preferable for 30 filters 19a and b to be detachable from the remaining portion of the set so that exhausted filters can be replaced by new filters without ever interrupting the flow of fluids to a patient. The set is shown with bag spike 16a in fluid communication with filter 19b. As an alternative it might 35 be desirable to house the dual filters 19a and b in a single permanent housing, especially in those cases where it is unlikely that any more than two filters will be needed.

Although blood/solution set 110 is illustrated as using a pair of anti-cross contamination valves 30 according to the present invention, in its most basic form this set does not necessarily need anti-cross contamination features in 5 order to gain the advantages of dual filters. In other words, the upper anti-cross contamination valve 30 could be replaced with a simple Y connector and the lower anti-cross contamination valve 30 could be replaced with a simple two-way valve of a type known in the art. In such a 10 configuration, the set would still suffer from potential cross-contamination between fluid supplies but would retain the advantage according to the present invention of being able to switch to a fresh filter, such as filter 19b, when the first filter 19a is exhausted. Thus, any suitable 15 connecting element can be substituted for the upper anti-cross contamination valve 30 that is illustrated.

Although the present invention has been illustrated as an anti-cross contamination urological set, extension tubing valve assembly, a Y-type blood/solution set and an 20 anti-cross contamination valve, it should be clear that various other modifications can be made to the present invention as herein above described and many apparently different embodiments of the same can be made without departing from this scope of the invention. For instance, 25 various known fluid delivery components (i.e., clamps, tubing, filters, connectors, etc.) can be assembled in various combinations with the anti-cross contamination valve of the present invention to produce a wide variety of medical fluid delivery systems needing a fail-safe against 30 cross contamination. The following is a partial list of some such medical fluid delivery systems which could utilize the anti-cross contamination valve of the present invention: nutritional pump sets, vented Y-type blood pump sets, arthroscopic irrigation fluid pump sets, cardiac 35 catheterization set, hypodermoclysis sets, Y-type connecting sets, venoset piggyback sets, irrigation Y-connectors, 4-lead transurethral resection sets, cystomanometer sets, Y-type blood volumetric pump sets, Y-type catheter extension

sets, mass infusion sets, acute peritoneal dialysis administration/drainage sets, Y-type wound irrigation sets, laparoscopic suction-irrigation sets, primary Y-type blood transfusion sets and endoscopic irrigation sets. Thus, the 5 present invention finds potential application in a wide variety of medical procedures including those relating to transurethral resection, endourology, arthoscopy, endoscopy, laparoscopy, endo-surgery, pelviscopic surgery, hysteroscopic surgery, to name but a few. Furthermore, 10 those skilled in the art will immediately appreciate that the principals of the present invention can be applied to produce anti-cross contamination valves having four or more ports, instead of three ports as shown in the described embodiments. The above description is intended to serve 15 only to aid those skilled in an art and an understanding of the invention and is not intended to limit the legal scope of the patent which is described solely by the claims as set forth below:

## THE CLAIMS

1. An anti-cross contamination valve comprising:  
a valve housing having only a plurality of first ports  
and a third port different from said plurality of first  
5 ports that all open into a hollow interior;  
a valve body rotatably mounted within said hollow  
interior and having at least one fluid passageway  
therethrough;  
a knob attached to said valve body and extending  
10 outside of said valve housing;  
said at least one passageway including a first fluid  
passageway that opens a first port of said plurality of  
first ports to said third port when said valve body is  
rotated to a first position with respect to said valve  
15 housing, all of said plurality of first ports, except said  
first port being closed when said valve body is in said  
first position;  
said at least one passageway including a second fluid  
passageway that opens a second port of said plurality of  
20 first ports to said third port when said valve body is  
rotated to a second position with respect to said valve  
housing, all of said plurality of first ports, except said  
second port being closed when said valve body is in said  
second position; and  
25 means for preventing said at least one fluid passageway  
from opening any of said plurality of first ports to one  
another.
2. The anti-cross contamination valve of claim 1,  
30 wherein said valve body has a third position that closes all  
of said plurality of first ports to said third port.
3. The anti-cross contamination valve of claim 2,  
35 wherein said knob includes an indicia that points at said  
first port when said valve body is in said first position  
and points at said second port when said valve body is in  
said second position.

4. The anti-cross contamination valve of claim 3,  
wherein said preventing means includes said valve housing  
having a first stop barrier and a second stop barrier;  
said valve body being restricted to rotating between  
5 said first stop barrier and said second stop barrier.

5. The anti-cross contamination valve of claim 2,  
wherein said at least one passageway, said first passageway  
and said second passageway are a single passageway.

10

6. The anti-cross contamination valve of claim 2,  
wherein said at least one passageway includes an elbow  
passageway; and

15 said first port is substantially aligned with said  
second port, which are both substantially orthogonal to said  
third port.

20 7. The anti-cross contamination valve of claim 2,  
wherein said first passageway is substantially parallel to  
said second passageway.

25 8. The anti-cross contamination valve of claim 7  
wherein said plurality of first ports includes at least one  
additional port; and  
said valve body includes at least three passageways  
substantially parallel to one another.

30 9. An anti-cross contamination Y-type blood/solution  
set comprising:  
a first length of tubing having a bag connector mounted  
on one end;  
a second length of tubing having a bag connector  
mounted on one end;  
35 an anti-cross contamination valve having a plurality of  
first ports that include a first port and a second port,  
said first port being attached to the other end of said  
first length of tubing, said second port being attached to

the other end of said second length of tubing, said valve also having a third port different from said plurality of first ports and means for preventing fluid flow between any of said plurality of first ports;

- 5           a drop former attached to said third port;
- a drip chamber attached to said drop former;
- a third length of tubing with one end attached to said drip chamber and an injection port mounted on its other end;
- 10          a clamp mounted around said third length of tubing; and
- a fourth length of tubing with one end attached to said injection port and a connector on its other end.

10. The anti-cross contamination Y-type blood/solution  
15 set of claim 9, wherein said valve includes:

- a valve housing having said first port, said second port and said third port that open into a hollow interior;
- a valve body rotatably mounted within said hollow interior and having at least one fluid passageway  
20 therethrough;
- a knob attached to said valve body and extending outside of said valve housing;
- said at least one passageway including a first fluid passageway that opens said first port to said third port  
25 when said valve body is rotated to a first position with respect to said valve housing, all of said plurality of first ports, except said first port, being closed when said valve body is in said first position;
- said at least one passageway including a second fluid passageway that opens said second port to said third port when said valve body is rotated to a second position with respect to said valve housing, all of said plurality of first ports, except said second port, being closed when said valve body is in said second position; and  
30
- means for preventing said at least one fluid passageway from opening any said plurality of first ports to one another.  
35

11. The anti-cross contamination Y-type blood/solution set of claim 10, wherein said valve body has a third position that closes all of said plurality of first ports and to said third port.

5

12. The anti-cross contamination Y-type blood/solution set of claim 11, wherein said knob includes an indicia that points at said first port when said valve body is in said first position and points at said second port when said 10 valve body is in said second position.

13. The anti-cross contamination Y-type blood/solution set of claim 12, wherein said preventing means includes said valve housing having a first stop barrier and a second stop 15 barrier;

    said valve body being restricted to rotating between said first stop barrier and said second stop barrier.

14. The anti-cross contamination Y-type blood/solution 20 set of claim 13, wherein said at least one passageway, said first passageway and said second passageway are a single passageway.

15. The anti-cross contamination Y-type blood/solution 25 set of claim 11, wherein said first passageway is substantially parallel to said second passageway.

16. A Y-type blood/solution set comprising:  
    a first length of tubing having a bag connector mounted 30 on one end;

    a second length of tubing having a bag connector mounted on one end;

    a connecting element with a first port attached to the other end of said first length of tubing, a second port 35 attached to the other end of said second length of tubing, and a third port;

    a valve having an inlet port, a first outlet port and a second outlet port, said inlet port being connected to said

third port of said connecting element; said valve having a first position in which said inlet port is connected with said first outlet port, and said valve having a second position in which said inlet port is connected with said 5 second outlet port;

a first filter with an outlet and an inlet connected to said first outlet port of said valve;

10 a second filter with an outlet and inlet connected to said second outlet port of said valve; said outlet of said first filter being merged with said outlet of said second filter into a merged outlet;

a drop former attached to said merged outlet;

a drip chamber attached to said drop former;

15 a third length of tubing with one end attached to said drip chamber and an injection port mounted on its other end; a clamp mounted around said third length of tubing; and a fourth length of tubing with one end attached to said injection port and a connector on its other end.

20 17. The Y-type blood/solution set of claim 16 wherein said connecting element is Y connector.

18. The Y-type blood/solution set of claim 16 wherein 25 said connecting element is an anti-cross contamination valve.

19. The Y-type blood/solution set of claim 16 wherein said valve is an anti-cross contamination valve.

30 20. The Y-type blood/solution set of claim 16 wherein said first filter is detachable and replaceable with a new filter.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US96/00708

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :A61M 5/14  
US CL :604/80

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 137/625, 525.12, 625.18, 625.41, 625.42, 625.46, 625.47; 604/9, 30, 42, 80, 81, 245-248, 256, 258, 323

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	US, A, 1,633,074 (R. H. DE MOTT) 21 June 1927, see entire reference.	1-15

A, P	US, A, 5,466,228 (EVANS) 14 November 1995, see entire reference.	1-15

 Further documents are listed in the continuation of Box C.  See patent family annex.

• Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
• "A" document defining the general state of the art which is not considered to be part of particular relevance	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
• "E" earlier document published on or after the international filing date	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
• "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"Z"	document member of the same patent family
• "O" document referring to an oral disclosure, use, exhibition or other means		
• "P" document published prior to the international filing date but later than the priority date claimed
